

Multi-layered phishing mitigations

The following real-world example shows how implementing **layers** of defences can help organisations (in this case a financial sector company of around 4,000 staff) defend themselves against phishing attacks. Reliance on any **single** layer would have missed some of the attacks, and cleaning infecting devices is costly and prohibitively time consuming.

1,800 malicious emails sent to the company in this campaign.

50 emails reached user inboxes.

14 emails were clicked on, launching malware.

1 instance of malware installed.
